01

Process

- For my final project, I focused on turning my midterm website into a more complete and interactive system.
- New Functions
- Favorites system (with persistent storage)
- Searching function
- Personalized home page
- LocalStorage
- Cart system with quantity and subtotal
- Checkout flow with form input
- Recipe pages
- Handling empty states across different pages

02

Source Code

```
const products = {
  "glass-bowl-set": {
    name: "Glass Bowl Set",
    price: "$18.00",
    category: "breakfast",
    image: "images/glass-bowl.jpg",
    description:
      "This clear glass bowl set is made for small, pretty meals. It works well for",
    details: [
      "Set of 4 small glass bowls",
      "Good for yogurt, fruit, oats, and desserts",
      "Clear design for a soft, clean table look",
      "Easy to wash and easy to style in photos"
    ]
  },
}
```

```
const users = JSON.parse(localStorage.getItem("tinyBitesUsers")) || [];

const matchedUser = users.find(function (user) {
  return user.email === email && user.password === password;
});

if (matchedUser) {
  localStorage.setItem("currentUser", JSON.stringify(matchedUser));
  alert("Login successful!");
  window.location.href = "home.html";
} else {
  alert("Email or password is incorrect.");
}
```

One thing I found surprisingly difficult was very small syntax errors.

For example, missing a comma or a bracket would break the entire script.

Sometimes the error message was not very clear, so I had to go back and check line by line.

This was frustrating, but it helped me understand how precise JavaScript needs to be.

Another important part of my code is using localStorage.

I used it to store user data like favorites and cart items.

This allowed the data to persist across pages, so users don't lose their selections when they navigate.

1st line retrieves stored user data from localStorage.

The data is stored as a JSON string, so I use JSON.parse to convert it back into a JavaScript array. If there is no data, it defaults to an empty array. After retrieving the data, I search through the array to find a matching user based on email and password. Once the user is authenticated, I store the current user in localStorage.

03 Issues

Favorites Page & Cart Page

One issue I had was that my favorites page would crash when there were no saved items. The page was trying to render data that didn't exist yet.

I fixed this by adding a condition to check if the favorites array was empty. If it is empty, the page shows a message instead of trying to render items.

```
if (favorites.length === 0) {  
    emptyState.style.display = "block";  
    return;  
}
```

Another issue was that users could still go to checkout even when the cart was empty.

I solved this by using a similar logic as the favorites fix.

I checked whether the cart had any items before allowing the user to proceed.

If the cart is empty, the checkout button is disabled.

```
if (cart.length === 0) {  
    cartItemsContainer.innerHTML = `  
        <div class="empty-cart">  
            <h3>Your cart is empty.</h3>  
            <p>Add something soft, tiny, and sweet to your cart.</p>  
            <a href="home.html">Go back to shop</a>  
        </div>  
    `;  
}
```

04

Takeaways

Through this project, I learned how to structure a multi-page website with shared data. I also learned how to debug JavaScript step by step instead of guessing. Another important takeaway is thinking about user experience — for example, what happens when there is no data.

- In the midterm, my site was mostly about layout and visual design. It had multiple pages, but the interactions were limited.
- In the final, I rebuilt many parts using JavaScript, so the site could actually respond to user actions.

Instead of organizing recipes only by meal time, I want to organize them by mood.

For example, “tired,” “calm,” or “need comfort.”

The system could recommend recipes based on how the user feels.

I want the cart to suggest items based on the recipes the user saved.

For example, if a user saves a recipe, the ingredients could be automatically added to the cart.

I would connect the site to a real backend instead of using `localStorage`, so that user data can persist across devices.
